BioOne Complete (complete.BioOne.org) is a full-text database of 200 subscribed and open-access titles in the biological, ecological, and environmental sciences published by nonprofit societies, associations, museums, institutions, and presses.

Your use of this PDF, the BioOne Complete website, and all posted and associated content indicates your acceptance of BioOne's Terms of Use, available at www.bioone.org/terms-of-use.

Usage of BioOne Complete content is strictly limited to personal, educational, and non - commercial use. Commercial inquiries or rights and permissions requests should be directed to the individual publisher as copyright holder.

BioOne sees sustainable scholarly publishing as an inherently collaborative enterprise connecting authors, nonprofit publishers, academic institutions, research libraries, and research funders in the common goal of maximizing access to critical research.

***Sarcocystis* sp. in Mountain Goats (*Oreamnos americanus*) in Washington: Prevalence and Search for the Definitive Host**

William J. Foreyt, Department of Veterinary Microbiology and Pathology, Washington State University, Pullman, Washington 99164, USA

ABSTRACT: During October and November 1986, *Sarcocystis* sp. was detected in 24 of 56 (43%) tongues from hunter-killed mountain goats (*Oreamnos americanus*) in Washington (USA). Sarcocysts had an unusual sessile polyp-shaped branched wall. Mean size of 154 sarcocysts was $71.3 \times 37.8 \mu\text{m}$ (range, 20 to 248×10 to $120 \mu\text{m}$), and the mean intensity was 2.3 (range, 1 to 28). In an attempt to identify the definitive host, infected tongues were fed to four coyotes (*Canis latrans*), eight domestic dogs, four domestic cats, three bears (*Ursus americanus*), two raccoons (*Procyon lotor*), two martens (*Martes americana*), two fishers (*Martes pennanti*), three skunks (*Mephitis mephitis*), five mink (*Mustela vison*), five ferrets (*Mustela putorius*), one pig-tail macaque (*Macaca nemestrina*), two red-tailed hawks (*Buteo jamaicensis*) and one great horned owl (*Bubo virginianus*). Oocysts or sporocysts were not detected in the feces of any host for ≤ 20 days after ingestion of the infected meat. The definitive host for *Sarcocystis* sp. in mountain goats was not identified.

Key words: *Sarcocystis* sp., mountain goat, *Oreamnos americanus*, prevalence, definitive host, experimental infections.

Sarcocystis spp. of ruminants are obligate two-host parasites that are commonly detected as sarcocysts in striated muscles (Dubey, 1976; Frenkel et al., 1979; Levine and Tadros, 1980; Levine, 1986; Levine and Ivens, 1986; Dubey et al., 1988). Carnivorous animals are definitive hosts that complete the life cycle by ingesting sarcocysts in infected meat. Ruminant intermediate hosts become infected by ingesting sporulated oocysts or sporocysts from the feces of infected carnivores.

Although *Sarcocystis* spp. have been described from a variety of wild ruminants (Dubey et al., 1988), there is only a single survey of *Sarcocystis* sp. in mountain goats (*Oreamnos americana*). In the one survey in Alberta (Canada), 11 of 15 mountain goats were infected, but details regarding the sarcocysts were not reported (Mahrt

and Colwell, 1980). The present study was undertaken to determine the prevalence and intensity of *Sarcocystis* sp. in mountain goats in Washington (USA), and an attempt was made to determine its definitive host.

Prior to the mountain goat hunting season in 1986 in the state of Washington, all modern firearms hunters with permits ($n = 200$) were sent a letter requesting the tongue from their goat if they were successful in killing a goat. Hunters were asked to chill the tongue on ice and send the tongue with an ice pack by priority mail or bus to Washington State University (Pullman, Washington 99164, USA). When tongues were received, sections approximately $1.5 \times 1.5 \times 0.5 \text{ cm}$ were removed from the dorsal anterior one-third and from the dorsal posterior one-third of the tongue for the histological sectioning, and the remaining parts of the tongue were stored at 4 C. Tongues were examined for sarcocysts the same day they were received after processing the tissues with a rapid freeze stain technique. The sections of tongue were mounted on brass chucks with Tissue-Tek O.C.T. compound (Miles Laboratories, Inc., Elkhart, Indiana 46515, USA), frozen at -30 C for 3 to 4 min, sectioned at $6 \mu\text{m}$, and mounted on a sub-slide with potassium dichromate and gelatin. Tissues were then fixed in a mixture of methanol (25 ml), formaldehyde (15 ml) and acetic acid (6 drops) for 3 to 4 min, and then stained with Mayer's hematoxylin for 3 min and eosin for 15 sec. Prepared tissues were examined microscopically at $100\times$ and the number of sarcocysts per cm^2 was determined. Length and width of sarcocysts were measured. For electron microscopy, small cubes of formalin-fixed tissue were transferred to 2% glutaralde-

croscopically sarcocysts resembled sarcocysts from other ruminant species (Fig. 2); however, at higher magnification (2,000 to 10,000 \times), unusual sessile polyp branching of the cyst wall was observed (Figs. 3, 4). The branching cell wall was approximately 5 μ m in diameter.

Oocysts or sporocysts of *Sarcocystis* sp. were not detected in feces of any mammal or bird fed infected tongues from mountain goats. The definitive host of *Sarcocystis* sp. in mountain goats was not determined.

Prevalence of *Sarcocystis* sp. (43%) in mountain goats in Washington was of sufficient magnitude and distribution that the definitive host must be present in western Washington. Likely definitive hosts are canine and feline species, particularly dogs,

coyotes and cats, or other carnivores such as black bears, raccoons and skunks. Although pieces of tongue from at least two infected goats were fed to each host, it is possible, but unlikely, that some sarcocysts were not viable. Only a few of the tongues received were odorous, with most of the tongues appearing fresh. In 1986, 125 mountain goats in Washington were killed by hunters, and 56 tongues (43%) were submitted.

The *Sarcocystis* sp. detected in the mountain goats that we examined is an unusual species when compared to existing descriptions of known species (Dubey et al., 1988). Most notable is the cyst wall which appears to be distinctly branched with individual sessile polyp-shaped projections. This type of cell wall has been

FIGURE 4. Transmission electron micrograph of the wall of *Sarcocystis* sp. in the tongue muscle of a mountain goat. Bcw, branching cyst wall; Bz, bradyzoite; Hmc, host muscle cell.

classified as Type 24 (Dubey et al., 1988), and has not been observed in other known *Sarcocystis* sp. (Mehlhorn et al., 1976; Dubey et al., 1988).

Sarcocystosis in cattle caused by *Sarcocystis bovis* can be a lethal disease. Schizogony in muscles causes rupture of blood vessels, anemia, incoordination and death (Briggs and Foreyt, 1985; Foreyt, 1986b). The impact of *Sarcocystis* sp. infection in mountain goats is unknown; however, there is the potential of *Sarcocystis* sp. as a mortality factor. The state of Washington has approximately 6,000 to 8,000 mountain goats, but mortality factors are essentially unknown (Johnson, 1983; Foreyt and Leathers, 1985; Dunbar et al., 1986). Further studies will clarify the importance and

epizootiology of *Sarcocystis* sp. in mountain goats.
