ABSTRACT

In Jun and Jul 2011 traps were deployed in Tuskegee National Forest, Macon County, Alabama to test the influence of chemical and visual cues on the capture of bark and ambrosia beetles (Coleoptera: Curculionidae: Scolytinae). The first experiment investigated the attractiveness of traps baited with different ratios of ethanol to methanol (0:100, 25:75, 50:50, 75:25, 100:0). No differences occurred in total Scolytinae trap captures for any of the various ratios of ethanol to methanol. The second experiment tested the attractiveness of ethanol-baited traps supplemented with light emitting diodes (LED) of various wavelengths to Scolytinae. Ethanol-baited traps supplemented with UV (395 nm) and green (525 nm) LEDs were more attractive than traps baited only with ethanol, but they were not more attractive than ethanol-baited traps supplemented with blue (470 nm) and red (625 nm) LEDs. This study indicates ethanol-baited traps supplemented with UV or green LEDs would be useful for detecting various Scolytinae.

Key Words: Alabama, attractants, LED, ethanol, methanol, UV, Scolytinae, traps

RESUMEN

En junio y julio del 2011, se utilizaron trampas en el Bosque Nacional de Tuskegee, en el condado de Macon, Alabama para probar la influencia de señales visuales y químicas sobre la captura de escarabajos ambrosia y de la corteza (Coleoptera: Curculionidae: Scolytinae). El primer experimento investigó el atractivo de las trampas cebadas con diferentes proporciones de etanol a metanol (0:100, 25:75, 50:50, 75:25, 100:0). No hubo una diferencia en el total de los escarabajos Scolytinae capturados en las trampas para todas las proporciones diferentes de etanol a metanol. El segundo experimento probó la atracción de los Scolytinae hacia las trampas cebadas con etanol y suplementadas con diodos emisores de luz (DEL) de diferentes longitudes de onda. Las trampas cebadas con etanol y suplementadas con UV (395 nm) y de DELs verdes (525 nm) fueron más atractivas que las trampas cebadas sólo con etanol, pero no fueron más atractivas que las trampas cebadas con etanol y suplementadas con DELs azules (470 nm) y rojos (625 nm). Este estudio indica que las trampas cebadas con el etanol y suplementadas con UV o DELs verdes serían útiles para la detección de varios Scolytinae.

Palabras Clave: Alabama, atrayentes, DEL, etanol, metanol, UV, Scolytinae, trampas

Se utilizaron trampas para determinar el atractivo de diferentes proporciones de etanol a metanol, y los diodos emisores de luz suplementarios (LED) de diferentes longitudes de onda a los coleópteros ambrosia y de la corteza (Coleoptera: Curculionidae: Scolytinae). El total de los Scolytinae capturados no fueron diferentes en cualquiera de las proporciones de etanol a metanol, sin embargo las trampas con UV suplementario y los LED verdes eran más atractivos que las trampas cebadas sólo con el etanol. Este estudio indica que las trampas cebadas con el etanol y suplementadas con UV o LEDs verdes serían útiles para la detección de varios Scolytinae.

The granulate ambrosia beetle, *Xylosandrus crassiusculus* (Motschulsky) (Coleoptera: Curculionidae: Scolytinae), is an ambrosia beetle of Asian origin that was first detected in the continental United States near Charleston, South Carolina (Anderson 1974). While *X. crassiusculus* is considered only a nuisance pest in some areas, this insect has caused significant losses (in excess of US $5,000 per nursery) in several nurseries across the southeastern United States and in Texas (Ree & Hunter 1995). The damage potential of this pest is further amplified by its ability to contribute to tree mortality, making it a significant concern in nursery settings.

In addition to olfactory cues, visual cues can also play a role during host selection by the Scolytinae. For instance, Da Silva et al. (2006) found green plastic bottle traps increased captures of *H. hampei* and other Scolytinae species compared to clear traps or transparent red traps. Similarly, Strom et al. (1999) demonstrated that both the southern pine beetle *Dendroctonus frontalis* (Zimmerman) and *Thanasimus dubius* (Fabricius) are affected by altering visual silhouettes on traps, finding that white paint and white trap paneling caught significantly fewer southern pine beetles than black or transparent coloration. In order to improve the detection and monitoring of various bark and ambrosia beetles, olfactory and visual cues were examined for their ability to enhance the attractiveness of ethanol-baited traps. Current management of ambrosia beetles in nurseries relies primarily on preventive treatments of insecticides applied to the trunks of trees, which can be improved with a greater knowledge of their seasonal activity and ecological interactions (Reding et al. 2010; Hudson & Mizell 1999).

### MATERIALS AND METHODS

**Experiment 1: Influence of Olfactory Cues**

The ability of methanol to enhance the attractiveness of ethanol to various Scolytinae was examined using Baker traps (Bambara et al. 2002; Oliver et al. 2004). Traps consisted of 2 L transparent plastic bottles cut with 3 windows above the bottom and hung from a shepherd’s hook, resulting in the traps being ~1.2 m above the ground. A mixture of water and liquid dish detergent (100:1; v:v) was added to the bottom of the container to subdue and kill the entering beetles. An 8 dram (29.5 ml) clear glass vial with a cotton wick (8 x 2 cm, Cotton® American Fiber and Finishing Inc., St. Albemarie, North Carolina) containing the volatile attractants (28 mL) held in place with parafilm was hung inside each individual bottle trap. Release rates for the volatiles were held constant at 3.8 g per day across all treatments by filling the uniform bottle (diameter 25 mm) completely with attractants (28 mL) held in place with parafilm. Traps were deployed in a randomized complete block design in Tuskegee National Forest, Macon County, Alabama (N 32° 29’ 19” W 85° 35’ 39”) from 12 Jun to 6 Jul 2011. Traps within each block were 6 m apart and were located in separate

...
parts of Tuskegee National Forest. The trap sites were densely populated with a mixture of pine and hardwood trees and were partially shaded. Traps were returned to the laboratory for specimen identification. *Xylosandrus crassiusculus* was identified to species, but the remaining specimens were grouped as total Scolytinae.

Experiment 2: Influence of Visual Cues

A second trapping experiment was conducted to examine the attractiveness of different wavelengths to *X. crassiusculus* and other Scolytinae. Embedded into the top of the aforementioned traps and spaced equally along the top rim of the bottle were four 1.5 watt light-emitting diode (LED) bulbs (Boesch Built LLC, Waterford Township, Michigan) powered by a 6 volt battery (McMaster-Carr® Elmhurst, Illinois) that was fastened directly underneath the traps. The LED color wavelengths included 395 nm (UV), 470 nm (blue), 525 nm (green), 625 nm (red), and a blank control. The LED lights were powered continuously throughout the entire duration of the experiment. Each trap was also baited with the aforementioned 95% ethanol lure. Traps were arranged in randomized complete blocks in Tuskegee National Forest. The field test was conducted from 12 Jun to 6 Jul 2011. There were 7 replicates per treatment.

**Statistics**

A one-way analysis of variance (ANOVA) was performed on log 10 (x +1) transformed data to compare the attractiveness of varying ratios of ethanol to methanol on Scolytinae trap captures (x = 0.05; PROC GLM; SAS Institute 2003). Differences between means were separated using Tukey’s honestly significant difference (HSD) test (P < 0.05). A one-way ANOVA (x = 0.05; PROC GLM; SAS 2003) on log 10 (x +1) transformed data and Tukey’s HSD test (P < 0.05) was also used to compare Scolytinae trap captures associated with the various LED colors.

**RESULTS**

Experiment 1: Influence of Olfactory Cues

No significant difference was detected in captures of all Scolytinae for traps baited with varying ratios of ethanol to methanol (100:0; 75:25; 50:50; 25:75; 0:100) (F 4,30 = 0.99, P = 0.43) (Fig. 1). No significant differences in mean (± SE) captures of *X. crassiusculus* were detected for traps baited with ethanol alone (0.57 ± 0.30), methanol alone (1.0 ± 0.38), or varying ratios of ethanol to methanol at 75:25 (1.0 ± 0.53), 50:50 (1.57 ± 0.53), 25:75 (0.86 ± 0.59) (F 4,30 = 0.54, P = 0.71).

**DISCUSSION**

Montgomery & Wargo (1983) did not find a mixture of 50% ethanol, 5% methanol, and 5% acetaldehyde to be more attractive than ethanol alone to various Scolytinae. Similarly, Ranger et al. (2010) found methanol-baited traps were more attractive to *Xylosandrus germanus* (Blandford) than acetaldehyde- and acetone-baited traps, but less attractive than ethanol-baited traps. Injecting sweetbay magnolia, *Magnolia virginiana* L.
(Magnoliales: Magnoliaceae), with methanol did not induce more ambrosia beetle attacks than a non-injected control, but over 120 attacks per plant were induced following ethanol-injection (Ranger et al. 2010). We found methanol alone was just as attractive as ethanol alone (Fig. 1), which differs from findings of other studies involving Scolytinae (Montgomery & Wargo 1983; Ranger et al. 2010). The lack of significant differences among any of the treatments involving various ratios of ethanol to methanol could be due to low trap counts from deploying traps after peak flight, which typically takes place in Mar to Apr in Macon County, Alabama (Gorzlancyk, pers. obs.) The relatively high release rate of ethanol and methanol from our lure apparatus may also have resulted in low trap counts. A positive concentration response to ethanol has been demonstrated for a few ambrosia beetles (Klimetzek et al. 1986; Ranger et al. 2011, 2012b), but too high of a release rate could have a repellent effect on ambrosia beetle orientation. Montgomery & Wargo (1983) found ethanol released at 2g/day attracted more Scolytinae than higher release rates. Thus, a mixture of ethanol and methanol cannot be recommended as an alternative or replacement of ethanol alone as an attractant for X. crassiusculus and other Scolytinae.

UV and household floodlights are currently used in general insect traps (Syms & Goodman 1987; Ferreira et al. 2012). Results from our current study demonstrated Scolytinae showed a higher attraction to ethanol-baited traps supplemented with green (525 nm) and UV (395 nm) LED lights compared to ethanol-baited traps alone. Attraction to green wavelengths has also been noted to occur in other members of the Curculionidae. For instance, Nakamoto & Kuba (2004) found evidence that the weevil Euichiropus postfasciatus (Fairmaire) (Coleoptera: Curculionidae) preferred green LEDs to the UV light traps.

Our results suggest ethanol-baited traps supplemented with green or UV LEDs would be useful for detecting various Scolytinae in a nursery or forest setting. The integration of specific LED wavelengths into other trap configurations could potentially yield species specific responses. A more detailed examination is therefore warranted to elucidate the physiological mechanisms underlying the role of visual cues in behavioral responses by X. crassiusculus and other Scolytinae.

ACKNOWLEDGMENTS

We thank Znar Barwary (Auburn University) for technical assistance and for reviewing earlier drafts of the manuscript. We also thank Jaeyoung Jeong for soldering and trap assembly. This work was funded by a USDA grant through the Specialty Crops Research Initiative awarded to Auburn University (USDA Grant No. 2010-51181-21169).
