BioOne Complete (complete.BioOne.org) is a full-text database of 200 subscribed and open-access titles in the biological, ecological, and environmental sciences published by nonprofit societies, associations, museums, institutions, and presses.

Your use of this PDF, the BioOne Complete website, and all posted and associated content indicates your acceptance of BioOne's Terms of Use, available at www.bioone.org/terms-o-use.

Usage of BioOne Complete content is strictly limited to personal, educational, and non-commercial use. Commercial inquiries or rights and permissions requests should be directed to the individual publisher as copyright holder.

BioOne sees sustainable scholarly publishing as an inherently collaborative enterprise connecting authors, nonprofit publishers, academic institutions, research libraries, and research funders in the common goal of maximizing access to critical research.
First Record of \textit{Lipoptena depressa} (Diptera: Hippoboscidae) from Alberta, Canada

\textbf{Murray J. Kennedy, Robert A. Newman,} Alberta Agriculture, Pathology Branch, 6909 \cdot 116 Street, Edmonton, Alberta, Canada T6H 4P2, and \textbf{G. A. Chalmers,} Alberta Agriculture, Regional Veterinary Laboratory, Postal Bag 3014, Lethbridge, Alberta, Canada T1J 4C7. \textsuperscript{1} Author to whom reprint requests should be addressed.

\textbf{ABSTRACT.} \textit{Lipoptena depressa} is reported for the first time from Alberta on a 2½-mo-old white-tailed deer fawn. This ked fly is one of four species occurring on deer in North America. The fawn had severe hemorrhagic enteritis of undetermined cause.

\textbf{Key words:} \textit{Odocoileus virginianus,} white-tailed deer, \textit{Lipoptena depressa,} Hippoboscidae, ked, case report.

\textit{Lipoptena depressa} (Say, 1823) Sacken, 1878 is reported from mule deer (\textit{Odocoileus hemionus}) (Bequaert, 1935, 1937, 1942, 1957; Spencer, 1938a, b; Cowan, 1943, 1946) and white-tailed deer (\textit{Odocoileus virginianus}) (Bequaert, 1957) from British Columbia. \textit{Lipoptena depressa} is reported also from Washington, Oregon, California, Idaho, Montana and South Dakota (Bequaert, 1937, 1942), Colorado (Eads and Campos, 1984), and Utah (Tipton and Saunders, 1971). Bequaert (1942) suggested that \textit{L. depressa} may occur in Alberta, but apparently it is not previously reported in Canada east of the Rocky Mountains. Maa (1969) erected two subspecies of \textit{L. depressa} to include specimens from the eastern slopes of the Rocky Mountains in Montana, Wyoming, South Dakota, and Nebraska (\textit{L. depressa depressa}), and those from the western slopes in British Columbia, Washington, Oregon, Idaho, and California (\textit{L. depressa pacifica}).

On 22 August 1986 a 2½-mo-old white-tailed deer fawn was found dead 9 km south of Cypris Hills, Alberta, Canada (49°33′N, 114°14′W) by a local rancher who contacted personnel of the Fish and Wildlife Division, Department of Energy and Natural Resources. The fawn was submitted to the Regional Veterinary Laboratory, Animal Health Division, Lethbridge, Alberta for examination. It had a severe hemorrhagic enteritis of undetermined cause. Bacteriological examinations of intestinal contents were negative for \textit{Salmonella} spp., \textit{Campylobacter} spp., and \textit{Yersinia} spp. and for toxins of \textit{Clostridium perfringens} Type C. Numerous keds (Hippoboscidae) were found on the skin. Representative samples were removed and stored in 70% ethanol for subsequent identification. Specimens were mounted and cleared in Berlese fluid and identified as \textit{Lipoptena depressa} following the descriptions of Bequaert (1937) and Maa (1969). Three female and two male specimens were sent to Dr. R. V. Peterson, Systematic Entomology Laboratory, U.S. National Museum of Natural History, Washington, D.C. who confirmed the identification. Voucher specimens are deposited in the U.S. National Museum of Natural History, but they were not assigned accession numbers.

Three additional species of ked flies occur on deer (\textit{Odocoileus} spp.) in North America. \textit{Lipoptena cervi}, introduced into the northeastern United States, is reported from Massachusetts, New Hampshire, and Pennsylvania (Bequaert, 1942). \textit{Lipoptena mazamae} occurs in the southeastern United States (Texas, Florida, Georgia, and South Carolina) and Central and South America (Bequaert, 1942; Samuel and Trainer, 1972). \textit{Neolipoptena ferrisi} occurs in southern British Columbia, Oregon, Colorado, California, North Dakota and Montana (Maa, 1969).
Lipoptena depressa is distributed primarily in the coastal region of British Columbia on O. hemionus columbianus. Apparently, N. ferrisi is distributed more commonly in the interior of British Columbia (Spencer, 1938a) on O. hemionus hemionus and O. hemionus columbianus. Spencer (1938a, b) and Cowan (1946) recovered low numbers of specimens from O. hemionus columbianus in the coastal regions of British Columbia. Spencer (1938a) believed that the distribution of the two species (L. depressa on the coast and N. ferrisi in the interior) probably resulted from climatic factors, rather than from host specificity. When both species occur on the same animal in the coastal regions L. depressa usually greatly outnumbers N. ferrisi (Spencer, 1938b).

The effects of this parasite on the fawn were not determined. It is conceivably that heavy infections could serve as an additional stress, contributing to poor condition or death of the host.

We thank Mr. Leo Dube, Fish and Wildlife Division, Lethbridge, Alberta for bringing this case to our attention.
