ABSTRACT: An adult female American alligator (*Alligator mississippiensis*) had diffuse, yellow, granular serosal thickening at necropsy. Light microscopic examination of affected stomach, small intestine and spleen revealed a chronic proliferative serositis associated with 3 to 15 μm eosinophilic extracellular globules identified histochemically and morphologically as egg yolk. The intracoelomic egg yolk was considered to be the cause of the serosal reaction.

Key words: *Alligator mississippiensis*, American alligator, crocodylian, egg yolk peritonitis, reptile pathology, chronic proliferative serositis, case report.

Egg yolk peritonitis, either sterile or contaminated by bacteria, is a common condition of domestic poultry and pet birds caused by abnormal presence of egg material or ruptured eggs in the coelomic cavity (Coutts, 1981; Blackmore, 1982). It has been reported in reptiles (Hamerton, 1938; Hime, 1976), including a broad-fronted crocodile (*Osteolaemus tetrapsis*) (Hamerton, 1938). This report describes an unusual, previously undocumented tissue reaction to intracoelomic egg yolk in an American alligator (*Alligator mississippiensis*).

During the 1980 summer breeding season, an active, adult (35.4 kg, 2.23 m) female alligator was killed near its nest at the Rockefeller Wildlife Refuge (Cameron Parish, Louisiana, USA; 29°N, 93°W). The nest contained about 40 eggs. The reptile was necropsied by wildlife biologists who reported that the only gross abnormality was a diffuse and finely granular yellow thickening of the mesentery and serosae of the stomach, intestines, spleen, kidneys, ovaries and oviducts.

Samples of small intestine, stomach, kidney and spleen were fixed in 10% neutral buffered formalin, routinely processed, embedded in paraffin, sectioned at 4 to 6 μm and stained with hematoxylin and eosin (H&E) and various special stains. Light microscopic examination showed that the only significant lesion was a marked chronic reactive serositis. Numerous finger-like, nonbranching projections composed of hy-

peritrophic mesothelial cells extended from the thickened serosa (Fig. 1). The haphazardly packed, polygonal to oval mesothelial cells were distended by confluent, clear cytoplasmic vacuoles; occasional cells had finely foamy cytoplasm. Cytoplasmic vacuoles were positive with oil-red-O staining (Sheehan and Hrapchak, 1980) but were negative with periodic acid-Schiff (PAS) reaction and Von Kossa's stain (Preece, 1972) alizarin-red-S stain (Thompson, 1966), and Ziehl-Neelsen, Prussian blue and Alcian blue stains (Luna, 1968).

Mesothelial cell nuclei were characterized by extreme pleomorphism. Oval and elliptical forms were present, as well as nuclei with irregular, undulating outlines. A few giant (10 to 40 μm), bizarre nuclei also were seen. Most nuclei had fine chromatin stippling with variable vesiculation. Mitotic figures were not seen in multiple sections.

Serosal vascularization was prominent.

Snook's reticulum stain (Luna, 1968) revealed a delicate, scanty lattice of reticulum fibers and Masson's trichrome stain (Luna, 1968) demonstrated slight to moderate amounts of perivascular collagen. A few small foci of mononuclear inflammatory cells and heterophils were scattered among the mesothelial cells.

Scattered throughout H&E sections were numerous, deeply eosinophilic, nonrefractile, extracellular, 3 to 15 μm diameter globules (Fig. 2). Some of the larger globules had faint concentric lamellations. Globules were PAS-positive but were negative with oil-red-O, Alcian blue, Von Kossa's, alizarin-red-S, Ziehl-Neelsen, and Prussian blue stains. Although the results of special stains of the globules did not correspond completely with those previously reported for snake egg yolk (Bellairs, 1959), the material was identified as egg yolk based on morphology (Bellairs, 1959; Hodges, 1974; Gilbert, 1979). The histo-

logic diagnosis was chronic diffuse proliferative serositis.

Because fresh tissue was not available for culture, the involvement of pathogenic microorganisms could not be excluded from the diagnosis. However, bacteria or fungi were not demonstrated with Gram or Ziehl-Neelsen stains or the PAS reaction. The paucity of inflammatory cell infiltrates in our case contrasts with the histological reaction that would be expected in bacterial and fungal infections. Many cases of egg peritonitis in pet birds are bacteriologically sterile (Blackmore, 1982).

We concluded that egg yolk elicited the serosal reaction in this alligator. As the oviductal ostia of the American alligator communicate freely with the coelomic cavity (Fox, 1977), escape or reflux by reverse peristalsis of ovulated ovarian follicles could easily occur. Alternately, traumatic rupture of an unovulated follicle also could liberate yolk material. This report emphasizes that egg yolk serositis should be considered in the differential diagnosis of serosal lesions in female crocodylians.

We wish to thank the Department of Veterinary Pathology, Armed Forces Institute of Pathology, Washington, D.C. for diagnostic consultation in this case.
