BioOne sees sustainable scholarly publishing as an inherently collaborative enterprise connecting authors, nonprofit publishers, academic institutions, research libraries, and research funders in the common goal of maximizing access to critical research.

Labramia ambondrombeensis (Sapotaceae), a Critically Endangered new species from Madagascar.

Aina Randriarisoa, Yamama Naciri & Laurent Gautier

Abstract

RANDRIARISOA, A., Y. NACIRI & L. GAUTIER (2020). *Labramia ambondrombeensis* (Sapotaceae), a Critically Endangered new species from Madagascar. *Candollea* 75: 83–87. In English, English and French abstracts. DOI: <http://dx.doi.org/10.15553/c2020v751a8>

Timber of the family *Sapotaceae* are appreciated for their physical properties internationally as well as locally, which often put a serious pressure on species survival. Taxonomic efforts are badly needed before producing reliable conservation assessments for the Malagasy species. In the framework of the revision of three related *Sapotaceae* genera, all endemic from Madagascar and surrounding islands of the Western Indian Ocean, a new species of *Labramia* A. DC. has been identified. It is described and illustrated here. *Labramia ambondrombeensis* L. Gaut. & Randriarisoa is one of the two *Labramia* species that have relatively small leaves. It is compared to *Labramia platanooides* Capuron ex Aubrév., the other small-leaved species from which it differs in leaf shape, pedicel size and ovary cell number. *Labramia ambondrombeensis* is known from a single collection that comes from a littoral forest in the Northeastern coast of the island, lacking any legal protection and is preliminary assessed as “Critically Endangered” using the IUCN Red List Criteria.

Résumé

RANDRIARISOA, A., Y. NACIRI & L. GAUTIER (2020). *Labramia ambondrombeensis* (Sapotaceae), une nouvelle espèce en danger critique d'extinction de Madagascar. *Candollea* 75: 83–87. En anglais, résumés anglais et français. DOI: <http://dx.doi.org/10.15553/c2020v751a8>

Le bois de la famille des *Sapotaceae* est apprécié pour ses propriétés mécaniques, dans le commerce international comme à l'échelon local, ce qui met en danger la survie des espèces de cette famille. Un important travail taxonomique est nécessaire avant de pouvoir produire des évaluations de menaces fiables pour les espèces malgaches. Dans le cadre de la révision taxonomique de trois genres endémiques de Madagascar et des îles périphériques, une nouvelle espèce de *Labramia* A. DC. a été identifiée. Elle est décrite et illustrée ici: *Labramia ambondrombeensis* L. Gaut. & Randriarisoa. C'est l'une des rares espèces de *Labramia* qui aient des feuilles relativement petites. Elle est comparée à *Labramia platanooides* Capuron ex Aubrév., qui est l'autre espèce à petites feuilles et qui diffère par la forme de ces dernières, la taille des pédicelles et le nombre de loges des ovaires. *Labramia ambondrombeensis* n'est connue que d'un seul spécimen qui provient d'une forêt littorale de la côte nord-est de l'île ne faisant l'objet d'aucune protection. Elle est préliminairement assignée à la catégorie “En danger critique d'extinction” selon les Critères de la Liste Rouge de l'IUCN.

Introduction

Sapotaceae is a well-defined tropical plant family of about 1250 species (PENNINGTON, 1991; GOVAERTS et al., 2001). Its members are mostly large trees that are highly valued for their mechanical properties and widely used in construction. Following the rosewood crisis (HASSOLD et al., 2016), they are, along with *Ebenaceae*, the next group likely to be severely affected by illegal logging in protected areas. Almost all species are characterized by a slow growth and long generation times and can be considered, from a conservation point of view, as markers of primary forests. However, classification based on morphological data is highly controversial in this family, and generic delimitations have always been a matter of debate (e.g. LAM, 1939; AUBRÉVILLE, 1964; BAEHNI, 1965; PENNINGTON, 1991): depending on the weight given to one or the other character, classification and number of accepted genera can change drastically. Those discrepancies do not allow conservation action to rely on strong taxonomic data. Thanks to molecular studies (e.g. ANDERBERG & SWENSON, 2003; SWENSON & ANDERBERG, 2005), nomenclatural stability is at hand and current efforts aim at revising this economically important and threatened family worldwide. In the *Flore de Madagascar et des Comores* (AUBRÉVILLE, 1974), the *Sapotaceae* family was represented by 11 genera and 84 species. The abundant material accumulated since clearly indicates the need of re-evaluating the taxonomy of this family for Madagascar, with the help of appropriate molecular methods. Numerous new taxa are suspected, some of them having been already described (e.g. GAUTIER et al., 2013; MACKINDER et al., 2016; GAUTIER & NACIRI, 2018).

The *Sapotaceae* genera present in Madagascar belong to the two main subfamilies: *Chrysophylloideae* (with the genera *Donella* Pierre ex Baill. and *Gambeya* Pierre), but mainly to *Sapotoideae*. Within *Sapotoideae*, three tribes are represented: *Sideroxyleae* (with *Sideroxylon* L.), the recently described endemic *Tsebonae* (GAUTIER et al., 2013) (with *Bemangidia* L. Gaut., *Capurodendron* Aubrév., and *Tsebona* Capuron) and *Sapoteae* (with *Mimusops* L., *Faucherea* Lecomte, *Labourdonnaisia* Bojer, *Labramia* A. DC., and *Manilkara* Adans.). The four latter genera belong to the subtribe *Manilkarineae* (PENNINGTON, 1991) which is characterized by a calyx arranged in two whorls of three sepals. A recent molecular study on the genus *Manilkara* worldwide (ARMSTRONG, 2010) including a restricted sample of *Faucherea*, *Labourdonnaisia* and *Labramia* pointed out that the relationships between these three genera are not well-resolved. As currently accepted, *Faucherea* is endemic to Madagascar, *Labourdonnaisia* being shared with the Mascarene Islands, and *Labramia* with the Comoros. Aiming at establishing conservation action based on strong taxonomic data, we undertook molecular studies and in-depth morphological analyses on a large sample of *Faucherea*, *Labourdonnaisia* and *Labramia* species, to investigate the generic circumscriptions and to solve

species delimitations within this group. The three genera have many features in common. However, *Labramia* clearly differs by the presence of a pair of dorsal appendages to the corolla lobes, a glabrous ovary, and seeds with a lateral scar almost as long as the seed. It is considered by PENNINGTON (1991) as a “well-knit group of [...] species”. Moreover, it appears as a well-supported monophyletic clade according to previous molecular study (ARMSTRONG, 2010). Our analyses based on an extended sampling and numerous nuclear genes give congruent results (Randriarisoa et al., unpubl. data).

There are currently nine known species of *Labramia*, among which eight are endemic to Madagascar (GAUTIER, 2003) and one to the Comoros (LABAT & PASCAL, 1997). In Madagascar, the geographical distribution of the genus extends mainly along the dense humid evergreen forest of the Eastern Domain (HUMBERT, 1955), but with one species found in the karstic limestone massifs in the West and the North. While revising the herbarium specimens of all *Labramia* species, many specimens could not be identified with confidence using the treatment of AUBRÉVILLE (1974). Among the material sorted as potential new species to be described, it was obvious that a *Labramia* collection from the littoral forest in the Northeastern coast clearly differed from all other specimens. Taking into account its rarity, the fragility of the habitat of its single known location (CONSIGLIO et al., 2006), and its clear morphological differences from other *Labramia* species, we propose here its formal description, anticipating the results of ongoing molecular studies which will ultimately provide a complete taxonomic revision of the genus. The new species is provided with a line drawing and its risk of extinction assessment using the IUCN Red List Categories and Criteria (IUCN, 2012).

Taxonomy

Labramia ambondrombeensis L. Gaut. & Randriarisoa, **sp. nov.** (Fig. 1).

Holotypus: MADAGASCAR. Reg. SAVA [Prov. Antsiranana]: Fiv. Vohemara, Fkt. Manakana, à l’E du village à Ambondrobe, 13°43’08”S 50°05’50”E, 13.III.2004, fl., Razakamalala, Rabevohitra & Faralaby 1077 (G [G00105531]!; iso-: MO-1979356!, P [P04568848]!, TEF!).

Labramia ambondrombeensis L. Gaut. & Randriarisoa is similar to *L. platanoides* Capuron ex Aubrév. in having relatively small leaves for the genus but differs by its cuneiform leaf blade (vs. obovate), by its longer flower pedicels (12–15 vs. 6–7 mm) and its 9–10 celled ovary (vs. 6 (–7) celled).

Tree (dimensions unknown), with white latex. Ultimate twigs 2 mm diameter, glabrous, brownish, with pales lenticels, soon becoming greyish and longitudinally ridged. Leaves

Fig. 1. – *Labramia ambondrombeensis* L. Gaut. & Randriarisoa. **A.** Flowering branch; **B.** Leaf with venation details (**a:** upper side; **b:** lower side); **C.** Flower; **D.** Flower in longitudinal section; **E.** Detached corolla spread opened (**c:** outer side, with appendages folded down and one lobe removed to show one lobe and one stamen; **d:** inner side, with two stamens removed to show inner side of lobes); **F.** Transversal section of the ovary. [Razakamalala et al. 1077, G] [Drawing: G. Loza]

alternate, petiole 10–15 × 1.1–1.6 mm, glabrous, with a median groove on upper side in continuation of the primary nerve; blade cuneiform, the widest portion 1/4 from the top and decreasing almost regularly to the acute base, apex rounded to slightly emarginated; (30–)40–65(–70) × 15–30 mm, entirely glabrous even when young, drying brown and discolours, darker above. Primary nerve prominent below, depressed above; secondary venation inconspicuous on upper side, visible on lower side, 10–12 pairs of secondaries, ascending with an angle of c. 30°–40°, straight and parallel to each other until their connexion through a marginal nerve 0.9 mm from the margin; intersecondaries present; tertiary venation faint. *Flowers* 1–3, fasciculate, borne axillary to the current year's leaves or above the scar of previous year's fallen leaves; flowering pedicels 12–15 × 0.6–0.8 mm, broadening to c. 1.2 mm in their upper third, entirely glabrous. *Sepals* 6, arranged in two valvate whorls; the three outer ones ovate, 4.5 × 2.0 mm, apex acute, base rounded, entirely glabrous, the three inner ones lanceolate, 4.5 × 1.5 mm, apex acute, base rounded, thinly puberulent on outer side, inner side glabrous. *Corolla* gamopetalous glabrous, tube 2.2 mm long, with a spherical lower part 1.2 mm long and 1.4 mm in diameter surrounding the ovary, then constricted to 1.0 mm in diameter, the upper part thicker and broadening up to the mouth, with 6 lanceolate lobes, 3.4 × 1.0 mm, apparently erect at anthesis, each with a pair of lateral appendages deeply incised in linear filaments up to 2.7 mm long. *Stamens* 6, filaments 0.4 mm broad at base, tapering to 0.2 mm at top, 0.8 mm long, attached to the top of the corolla tube. Anther pairs narrowly sagittate, medifixed, extrorse, 2.2 × 0.8 mm at the broadest, concealed in the corolla lobes. *Staminodes* absent or if present then 6, vestigial, alternate with respect to petals and stamens, triangular, 0.5 × 0.5 mm, glabrous. *Ovary* broadly conical, 2.2 mm high × 1.2 mm in diam., glabrous, 9–10 celled with 1 ovule per cell, style narrowly conical 4 mm long, 1.3 mm diam. at base, 0.4 mm below stigma, glabrous. *Fruit* unknown.

Etymology. – This species epithet refers to the name of the village of Ambondrombe, near the littoral forest where the type specimen was collected.

Phenology. – The flowering specimen was collected in March.

Distribution and Ecology. – *Labramia ambondrombeensis* is only known from the type collection in Northeastern Madagascar, at the extreme North of the Eastern Phytogeographic Domain, near the southern limit of the Northern Sector of the Western Domain (HUBBERT, 1955). It was collected in a littoral forest on sands.

Conservation status. – The new species is known only from a single location in a little patch of unprotected littoral forest. Littoral forest is under major threat of logging and habitat conversion (CONSIGLIO et al., 2006). With only one known location and an AOO of 4 km², outside of the protected area network, *L. ambondrombeensis* is assigned a provisional status of “Critically Endangered” [CR B1ab(i,ii,iii)+2ab(i,ii,iii)] using the IUCN Red List Criteria (IUCN, 2012).

Notes. – *Labramia ambondrombeensis* is clearly distinct from most other *Labramia* species because of its small leaves (4.0–6.5 cm long). The only other species, also occurring in the North of Madagascar, with such small leaves is *L. platanoides* Capuron ex Aubrév. Apart from the morphological distinctions, habitat preferences distinguish the two species: while the specimen of *Labramia ambondrombeensis* was collected in littoral forest on sand, *Labramia platanoides* is known to have a predilection for dry deciduous to semi-deciduous forests on limestone (AUBREVILLE, 1974). *Labramia ambondrombeensis* is not the only species in littoral forest; further south, under per-humid climate, one finds *L. bojeri* with much larger leaves (up to 25 cm long).

Acknowledgments

The authors would like to thank Gabriella Loza for her nice drawing of the new species and the P, MO and TEF herbaria for providing loans and/or information. AR is funded by the Bourses d'excellence de la Confédération suisse pour chercheurs étrangers. The project *Understanding Madagascar Sapotaceae* is funded by the Franklinia foundation. We would like also to thank Martin Callmänder and Lorenzo Ramella for comments and suggestions.
