Abstract

Lysosomal and microsomal acid phosphatase activity was estimated in midgut tissue of silkworm larvae, *Bombyx mori* L. (Lepidoptera: Bombycidae), after induced oxidative stress by D-galactose. The larvae were simultaneously were treated with ethanolic extracts of *Bacopa monniera* and *Lactuca sativa* to study their antioxidant properties. Lipid peroxidation and fluorescence was measured to analyze extent of oxidative stress. The ethanolic extract of *Lactuca sativa* was found to be more effective in protecting membranes against oxidative stress than *Bacopa monniera*.

Key words: D-galactose, *Bacopa monniera* and *Lactuca sativa*

Abbreviations: ACP, acid phosphatase; ROS, reactive oxygen species

Introduction

Oxidative stress is caused by free radicals such as reactive oxygen species (ROS), which includes superoxide (O$_2^-$), peroxyl, alkoxyl, hydroxyl and nitric oxide. ROS are characterized by presence of an unpaired electron in their outer orbit. In addition to these ROS radicals in living organisms, there are other ROS non-radicals such as the singlet oxygen (^1O$_2$), hydrogen peroxide and hypochlorous acid (Pietta, 2000). Small quantities of ROS are formed spontaneously under normal conditions as by products of redox processes such as oxidative phosphorylation in the mitochondria and β-oxidation of fatty acids. However, the production of ROS is increased when the organism is subjected to irradiation, chemicals or infection (Knapowski et al. 2002). Overproduction of ROS damages cellular lipids, nucleic acids, proteins and leads to lipid peroxidation, genome instability or gene mutation; protein carbonyl formation and enzymatic inactivity resulting in degenerative processes leading to aging (Martin et al. 1996; Berlett and Standtman 1997; Finkel and Halbroook 2000). To defend against the ROS formed, animal cells use three enzymes, superoxide dismutase, catalase and glutathione peroxidase. Superoxide dismutase converts superoxide anion to oxygen and hydrogen peroxide. In biological tissues superoxide can also be converted nonenzymically into the nonradical species hydrogen peroxide and singlet oxygen (Steinbeck et al. 1993). Catalase reduces hydrogen peroxide to water and oxygen (Fridovich 1978). Glutathione peroxidase neutralizes hydrogen peroxide by taking hydrogens from two glutathione molecules resulting in two H$_2$O and one molecule of an oxidized form of glutathione. Besides these cellular antioxidant enzymes there are non-enzyme antioxidants such as α-tocopherol, β-carotin, lycopene and ascorbic acid.

Evidence has accumulated showing that plant polyphenols are an important class of defense antioxidants. These compounds are widespread virtually in all plant foods, often at high levels, and include phenols, phenolic acids, flavonoids, tannins and lignans. Acid phosphatase (ACP) is a lysosomal enzyme that catalyzes the hydrolysis of variety of phosphate monoesters and phosphoprotein in an acidic medium. Phosphatases are capable of transphosphorylation in addition to hydrolysis. Phosphatases thus play an important role in the metabolism of carbohydrates, phospholipids and nucleotides (Hollander 1971; Van Rees 1888; Crossley 1964, 1965; Givindwar and Bhawane 1989, Bhawane and Bhanot 1989, 1990, 1994, Bhanot and Bhawane 1991). Acid phosphatase is found mainly in cytosol of midgut tissue cells of Diptera (Ferreira and Terra 1980) and Lepidoptera (Santos and Terra 1984). Malondialdehyde and 4-hydroxynonenal are the products of lipid peroxidation. Malondialdehyde and lipofuscin granules are the indicators of oxidative stress and increase with age (Nakano et al. 1995; Sitte et al. 2001).

In present investigation the silkworm Bombyx mori is used to study the effects of D-galactose-induced oxidative stress and the antioxidant properties of ethanolic extracts of Bacopa monniera and Lactuca sativa. Alcoholic extracts of L. sativa and B. monniera contain polyphenols and flavonoids.
It is well known that polyphenols and flavonoids have antioxidant properties. Previous studies suggest that antioxidant polyphenol compounds found in fruits and vegetables may reverse aging (Joseph et al. 2005). *L. sativa* contains quercetin a flavonol-type flavonoid ubiquitously present in fruits and vegetables (Bilyk and Supers 1985; Zhang, 2005). Quercetin has the antioxidant property of scavenging free radicals such as superoxide radicals, peroxyl and hydroxyl radicals generated in various cellular processes (Dok-Go et al. 2003; Ioku et al. 1995; Kefalas et al. 2003). *B. monniera* contains mixture of triterpenoid saponins and bacosides (Chatterjee et al. 1963). Previous studies on ethanolic extracts of *L. sativa* have shown neuroprotective effects by strengthening the antioxidant system of nervous cells in mice (Deshmukh et al. 2007). An ethanolic extract of *B. monniera* has shown to reduce lipid peroxidation and promotes antioxidant status (Rohini et al. 2004). In insects, the midgut is a dynamic tissue as it is the only section of the alimentary canal where the process of digestion and absorption of digested food takes place. Therefore this is the active organ in insect body organization selected in this study.

**Material and Methods**

**Preparation of extracts**

Fresh leaves of *Bacopa monniera* and *Lactuca sativa* were collected and washed with distilled water and shade dried. After complete drying, leaves were powdered and kept in alcohol for 72 hours for extraction. The alcohol was allowed to evaporate and the resulting paste was collected and stored for further use.

**Silkworm rearing and administration of dose**

The silkworm *B. mori* larvae of race PM were reared according to standard methods (Krishanaswami et al. 1978). Treatment was given feeding the fifth instar larvae for the first three days by dipping and air-drying mulberry leaves of equal weight in various solutions of dosages prepared by dissolving D-galactose and ethanolic herbal extracts (Table 1). Control mulberry leaves were dipped in distilled water. The larvae were treated for first three days of fifth instar. On the fourth day, midgut tissue was dissected from larvae.

**Sub-cellular fractionation**

The midgut tissue was homogenized in 0.25 M sucrose containing 1mM EDTA. The homogenates were subjected to sub-cellular fractionation at 4°C. The homogenate was first centrifuged at 1,000 g to remove unbroken cells and nuclei. The pellet was discarded and the supernatant was again centrifuged at 10,000 g to separate lysosomes and mitochondria. The supernatant was used as microsomal enzyme source. The pellet was resuspended in 0.25M sucrose containing 1mM EDTA that served as lysosomal enzyme source.

Measurement of lipid peroxidation and fluorescence

Lipid peroxidation was estimated using TCA-TBA-HCl reagent. The reaction mixture contained 1 ml homogenate prepared in 0.8% NaCl and 2 ml of TCA-TBA-HCl reagent. The tubes were kept in boiling water bath for 10 min. Tubes were removed and cooled and centrifuged, absorbance was measured at 532 nm using a spectrophotometer. Malondialdehyde was estimated using the extinction coefficient $1.56 \times 10^5 / \text{M MDA/cm}^2$.

Fluorescence was measured using the Dillard and Tappel method (1971). One ml of homogenate was extracted at room temperature with 6 ml of chloroform and methanol mixture (2:1) the extracts were centrifuged for two min. at 1500 g. After mixing briefly with 6 ml of water two layers were formed. Four ml of the upper chloroform layer was removed to a test tube and 0.4 ml methanol was added. The fluorescence was determined using a photofluorometer calibrated with quinine sulfate at 1mg/ml.

Estimation of ACP

The acid phosphatase activity was estimated using the Linhardt and Walter method. The assay mixture contained 0.2 ml of enzyme source and 0.8 ml of citrate buffer (pH 4.0) containing $5.5 \times 10^{-3}$ M p-nitrophenyl phosphate as substrate. The assay tubes were incubated for 30 min. at 40°C. The reaction was stopped by adding 4 ml of 0.1 N NaOH. The absorbance was measured at 405 nm. Zero absorbance was adjusted by control devoid of enzyme source. The protein content in enzyme sources was estimated by the method of Lowry et al. (1951).

Results and Discussion

D-galactose is a reducing sugar that accelerates the process of aging by increasing oxidative stress as was observed in Drosophila melanogaster and Musca domestica (Xu et al. 2004). With age, lysosomes of postmitotic cells increasingly become full with aggregates of oxidized, glycated and crosslinked proteins that are
resistant to enzymatic degradation, which is called lipofuscin. Accumulation of lipofuscin is a major manifestation of aging in insects, the concentration of fluorescent age pigment increases with age in tissues (Sohal 1981).

The results show a significant increase ($p < 0.001$) in midgut lipid peroxidation and fluorescent products in D-galactose treated larvae (Figures 1 and 2), indicating the increased oxidative stress due to D-galactose. Lysosomal acid phosphatase activity in midgut tissue of D-galactose treated larvae was decreased significantly, but the microsomal ACP activity was increased significantly ($p < 0.001$) as compared to the control group (Figure 3).

Cellular organelles are surrounded with lipid membranes that get damaged due to lipid peroxidation which is result of oxidative stress. Damaged membrane loses its fluidity and integrity. The biological membranes can be disrupted by degrading phospholipids that are the primary molecular component of biological membranes (Tappel 1980; Donato and Sohal 1981). Lysosomal acid phosphatase is transported as a transmembrane protein to dense lysosomes, the pathway of lysosomal ACP to lysosomes include the passage through the plasma membrane (Martin et al. 1989).

Injured lysosomes release hydrolytic enzymes in cytoplasm leading to auto degradation of cellular proteins, damage to endoplasmic reticulum interferes with protein synthesis and intracellular transport of vital compounds (Zs-Nagy 1979 and 2002). Lipid peroxidation in membrane lipids plays an important role in cell physiology and pathology, there are number of membrane bound enzymes and their activity is altered by lipid peroxidation. Lipid peroxidation and fluorescent products were lower in midgut of larvae treated with herbal extract than the D-galactose treated group showing their antioxidant properties. There was no significant difference in fluorescent products as compared with control group. The ethanolic extract of Bacopa monniera was found to be less effective in protecting lipids against lipid peroxidation than the Lactuca sativa extract. Simultaneous treatments with extracts of B. monniera or L. sativa with D-galactose resulted in an increase in the lysosomal ACP activity (Figure 3) than D-galactose treated group, where as the microsomal ACP activity was significantly less.

The results showed that the ethanolic extract of L. sativa was more effective in protecting the lysosomal membrane integrity than B. monniera. Overall lysosomal ACP activity was found to be higher when there is a low level of oxidative stress. At higher levels of oxidative stress the lysosomal membrane was damaged that resulted in an increase in microsomal ACP activity.
